

THE COMMISSIONER OF PATENTS AND TRADEMARKS Washington, D. C. 20231

Gentlemen:

Enclosed for filing is the Patent Application of John Sobota, Jason Gosiør Louis Garner, and Colin Broughton entitled:

RADIO FREQUENCY REMOTE GAME CONTROLLER.

Enclosed are:

- 1. A declaration and power of attorney;
- 2. A copy of the patent specification and claims;
- 3. 1 page of informal drawing; and
- 4. A verified statement to establish small entity status.

The filing fee has been calculated as follows:

Filing fee Additional Independent Claims (0) Claims in excess of 20 (0)

\$395.00

\$395.00

Total enclosed

RADIO FREQUENCY REMOTE GAME CONTROLLER

BACKGROUND OF THE INVENTION

The invention described herein relates to the field of remote game controllers for operating electronic games. More particularly, the invention relates to a radio frequency operated remote game controller for operating an electronic game device.

Electronic games use software and hardware devices to simulate game situations and experiences through visual and audio stimulus. Such games provide interactivity with a person through a controller which permits the person to change the game direction or response. Many games are fast moving and draw the user into fast moving responses which integrate the person into the game. Popular games require fast reflexive responses to the game situation and format, and require the transmission of large data sets. Any interruption of such game is disruptive to the person's enjoyment and is highly undesirable.

Conventional game controllers are typically hard wired to the hardware or alternatively transmit data signals with infrared frequency transmission. Hardwired controllers are capable of reliable, fast signal communication, however such controllers require wires leading from the controller to the hardware. Such wires present a safety hazard because persons and pets can trip over the wires, and further limit the operating mobility of the user relative to a central controller.

Infrared frequency ("IR") controllers are conventionally used in many remote control devices including controllers for televisions, stereos, and other

10

15

20

remote controlled devices. IR controllers are undesirable because a moving person or pet can interrupt the communication link with the hardware at the most undesirable time during the game play, and because the IR controller must be pointed substantially at the hardware to maintain the communication link.

Additionally, the number of channels open to IR controllers within a room is limited because the IR controller light sources illuminate the room with scattered light, thereby reducing the capability of the room to transmit any additional concurrent IR communications. Although IR light can be modulated, the number of effective communication lines operable within a single room is limited.

Certain multiple game devices have been proposed to permit simultaneous, multiple user operation of a game system, however such systems typically hardwire the controllers to the central control system and to other controllers. For example, United States Patent No. 5,538,255 to Barker (1992) disclosed a system for a remote controlled multiplayer video game. United States Patent No. 5,292,125 to Hochstein et al. (1991) disclosed a video game communicator electrically connected with telephone lines, and United States Patent No. 4,372,558 to Shimamoto et al. (1979) also disclosed a remote game apparatus using a telephone line as the communication means.

United States Patent No. 4,531,740 to Green et al. (1985) disclosed a remote controller system for a video computer game which used radio frequency ("RF") transmission as a communication mechanism and required a reset mechanism on a control center. Data was transmitted through different

10

15

20

channels, significantly limiting the flexibility of a controller and limiting the number of users able to simultaneously operate the game system.

Another radio broadcast system was disclosed in United States Patent No. 5,806,849 to Rutkowski (1998) wherein long range signal transmission was proposed. Such system also depended on multiple channel transmission and used a single receiver to poll individual channels. Such polling requirement significantly increases delay in signal processing and limits high data transmission required in remote game transmission.

Conventional game controller systems often provide multi-user capabilities and power efficiency based on frequency domain multiplexing ("FDM"). FDM uses multiple frequencies or channels to carry multiple signals through a common airspace, or one signal per channel. Systems incorporating FDM are undesirable because of additional cost and complexity, and because a larger transmission spectrum is required for the communication footprint. This requirement increases the possibility of signal interference from other signals, and with the possibility of controller interference with other products and appliances.

Accordingly, a need exists for an improved game controller system which does not have the limitations of prior art controllers. The system should efficiently and accurately transmit large quantities of data and should provide flexibility to permit operation by multiple users.

10

15

20

SUMMARY OF THE INVENTION

The invention provides a system for communicating between a person and an electronic game device. The game controller comprises a housing, a sensor attached to the housing and responsive to operation by the person to generate signals, a radio frequency sender engaged with the sensor which is capable of time domain multiplexed transmission of the signals, and a radio frequency receiver engaged with the electronic game device for receiving the signals from the radio frequency sender.

In other embodiments, the invention provides a game controller system for communicating between at least two persons and an electronic game device which comprises a housing, a sensor engaged with the housing and responsive to operation by the persons to generate signals, a radio frequency sender engaged with the sensor for time domain multiplexed transmission of the signals, and a radio frequency receiver engaged with the electronic game device for receiving the signals from the radio frequency sender.

The method of the invention is practiced by operating a sensor engaged with a housing to generate signals in response to operation by the person, by detecting the signals with a radio frequency sender engaged with the sensor; by operating the radio frequency sender to transmit the signals with time domain multiplexing, and receiving the radio frequency sender signals with a radio frequency receiver engaged with the electronic game device.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 illustrates a controller having a transmitter for sending signals to a RF receiver.

Figure 1a illustrates multiple controllers engaged with a single receiver.

Figure 2 illustrates multiple controllers engaged with multiple receivers.

Figure 2a illustrates multiple controllers engaged with a single game system having multiple receiver functions.

Figure 3 illustrates a one second (1000mS) in which are transmitted eleven 1mS data packets (not to scale).

Figure 4 represents a collision between two transmitters operating on the same channel.

Figure 5 compares RF with IR signal transmission.

Figure 6 illustrates a combination of time domain multiplexing in one direction with IR or another signal transmission in an opposing direction.

10

5

DESCRIPTION OF THE PREFERRED EMBODIMENTS

The invention provides a system for remote communication between a user and an electronic game device. The invention uniquely provides uninterrupted RF data communication between multiple users and time domain multiplexed ("TDM") transmission within one or more channels to save battery power and to enhance data transmission with a reduced spectral footprint and diminished radiated energy. The invention provides unique capabilities to transmit data at fast rates, provides for "burst" transmissions, and provides for

10

15

20

receiver 16 and game device 17.

addressed communications between one or more transmitters and one or more receivers.

As shown in Figure 1, controller 10 has sensors or keys 12 which perform different operating functions. Keys 12 can be responsive to pressure, audible sounds, light, movement, and other stimulus. Figure 1 illustrates an RF sender such as transmitter 14 which is attached to controller 10 and broadcasts signals to RF receiver 16 integrated with electronic game device 17. RF receiver 16 can be hard-wired into electronic game device 17 or can comprise a remotely connected or plug-in module attachable to electronic game device 17.

Transmitter 14 can be mated with receiver 16 by indexed names, signals, or selected addresses by assigning unique address codes to each controller. As shown in Figure 1a, multiple controllers 10 can be engaged with a single

As shown in Figure 2, multiple controllers 10 with corresponding transmitters 14 can be integrated with multiple receivers 16 to create game system 18. Alternatively, one or more receivers 16 can operate with one or more controllers 10 in different combinations of the invention. For example, as illustrated in Figure 2a, two controllers 10 can be engaged with a single game device 17 having two receiver functions 16.

As used herein, the term "TDM" refers to the use of different intervals of time to carry multiple signals on the same RF frequency or channel or other medium. Because each signal requires only a small percentage of time within a discrete time interval, the invention permits many signals to share the same

10

channel. TDM is possible over an RF channel, a single wire, or an optical link.

Accordingly, the use of TDM for game applications is extendible to transmissions other than exclusive RF transmissions.

The invention is particularly suited to game applications because of the random timing and low frequency of controller events required for game applications. Controller events are defined as a change in state of the set defined by controller keys 12. For example, if controller 10 has sixteen keys, an event occurs when the state of any key 12 changes. To ensure synchronization between transmitter 14 and receiver 16, the entire state of keys 12 is transmitted each time an event occurs. The following example represents operation of one key 16 in three states and two events:

Frank Transmitted

| | State: | Event Transmitted. |
|----|---------------------|---------------------|
| | 0000 0000 0000 0000 | |
| | 0000 1000 0000 0000 | 0000 1000 0000 0000 |
| 15 | 0000 0000 0000 0000 | 0000 0000 0000 0000 |

The following example represents operation of two keys 16 being pressed and released:

| | State: | Event Transmitted: |
|----|---|--|
| 20 | 0000 0000 0000 0000 0000 0000 0100 0000 1000 0000 0100 0000 1000 0000 0000 0000 0000 0000 0000 0000 | 0000 0000 0100 0000 1000 0000 0100 0000 1000 0000 0000 0000 0000 0000 0000 0000 |
| | | |

A packet of data, representing the state of all keys 12, is transmitted from transmitter 14 to receiver 16 each time an event occurs. In another embodiment

10

15

20

of the invention, the packet size of transmitted data can be reduced by transmitting only the changes in the data transmission.

Figure 3 represents a single second of time in which eleven 1mS packets are transmitted (not to scale). This can be accomplished with a 56 kbps (56,000 bits per second) transmission rate because in 1mS 56 bits can be transmitted to provide for sixteen bits of state information in addition to address and other overhead information.

For game operations, the number of events and required number of packets should not ordinarily exceed thirty per second. Assuming 1mS packets, 30/1000 of the second is used and 970/1000 of the second is available for transmission of additional data on the same channel.

By using TDM in the transmission of data and signals, controls should be implemented to control and manage "collisions". A collision occurs when data from one signal collides with or interrupts data from another signal on the common medium. Although many different techniques can be used to avoid or to control collisions, one embodiment of the invention uses random delay resend to transmit a copy of each packet after a random delay. Figure 4 represents such transmission wherein two transmitters 14 are located on the same RF channel. As illustrated, a data collision occurs on the first packets A1 and B1 because both transmitters 14 attempt to transmit at the same time. Receiver 16 can detect collisions through error detection techniques such as checksums, parity, CRC, or other techniques. Collision detection by receiver 16 causes receiver 16 to ignore the damaged data, and the copies of the respective data

10

15

20

packets are retransmitted after a random delay. In Figure 4, A1c is retransmitted 2mS after the end of A1, and B1c is retransmitted 5mS after the end of B1. If the original packets (A1 and B1) have not collided, receiver 16 will ignore the retransmitted copies because such copies can be marked accordingly.

Synchronous communication involves slices of time which are clearly identified and assigned to respective data streams. Because of this clean allocation of time slots to data streams, collisions are virtually eliminated. This type of communication is not desirable for RF gaming because a data link would be required between controllers in order to synchronize the timing of transmissions. This requirement would significantly complicate the system.

Accordingly, preferred implementations of TDM involve collision management techniques using redundant, random-delayed resends, or listen-before-send techniques.

A listening function can be used to "listen-before-send" without requiring duplex or bi-directional communication. This feature of the invention simplifies data transmission by permitting transmission in one direction instead of in two directions. A transmitter 14 that wishes to transmit can first monitor the channel to determine whether traffic exists. After the channel is confirmed as clear, transmitter 14 can transmit as a simplex or one direction communication. Other techniques can be derived to provide for signal transmission in one direction between transmitter 14 and receiver 16, or vice versa. If confirmation of signal transmission was desired, bi-directional transmission could be included in an alternative embodiment of the invention.

10

15

20

In another embodiment of the invention, time domain multiplexing can be combined with frequency domain multiplexing so that multiple channels are used in combination with multiple users operating on each channel. This combination would permit two or more transmitters 14 to transmit data on each channel while permitting expansion of the signal transmission capabilities over multiple channels.

The invention can use "burst" transmission wherein transmitter 14 does not continuously transmit data packets, but transmits data in a plurality of relatively short, discrete time interval "bursts". Transmitter 14 is disabled whenever a packet is not being transmitted and is only enhanced during very brief periods ("bursts") during which a packet is transmitted. The RF carrier is therefore suppressed at all times except during such bursts. This feature of the invention reduces the actual operation time of transmitter 14, and reduces the energy required by controller 10. Accordingly, battery life is extended and active gaming play time interruption is reduced. Moreover, the amount of energy radiated by controller 10 is reduced, therefore reducing interference.

In one application of the invention, one or more controllers 10 can transmit multiple data sets on a single channel. In another application, one or more controllers 10 are capable of transmitting on different channels simultaneously. Additionally, controller 10 is capable of changing from one channel to another, thereby providing flexibility in game operation between multiple users. A user can press a "channel key" on controller 10, and controller 10 then broadcasts a command on all channels telling the mated receiver 16 to

10

15

20

change to channel "A". Controller 10 then switches to channel "A". The mated receiver 16 has already received the command and also switches to channel "A". Because the broadcast signal was sent on all channels, the prior operating channel of receiver 16 does not inhibit the ability of controller 10 to connect with receiver 16. All other non-mated receivers 16 also receive the same broadcast signal, however the other receivers 16 ignore such broadcast signal because such receivers are mated with other controllers 10.

Although different RF frequencies are possible, frequencies exceeding 300 MHz are preferred. This frequency range provides another advantage of eliminating the need for an external antenna with controller 10 or with receiver 16. The absence of required antennas is significant for providing easy and damage free operation of game systems. Operation of the invention at high frequency enables high data rates (56,000 bps and higher) which in turn enables very short burst transmissions. These short burst transmissions enable time domain multiplexing, enhance power efficiencies, and reduce the radiated RF energy. This combination also reduces the possibility of potential interference.

The invention operates at high data transmission rates which reduces delay in signal transmission and enhances game play response. Rates of 56,000 bps permit the transmission of 56 bits in 1mS. A 1mS transmission, for example, can accommodate a 56 bit packet comprised of a 16 bit event plut 40 bits of address, framing and error detection/correction information. For infrared transmission typically used in conventional game systems, the same event having one-half the bits may require 3mS, thereby establishing RF transmission

15

20

in the invention as a significantly faster (by three hundred percent) mechanism for transmitting data in game operations. Burst transmission of such 1mS packets each containing, for example, 56 bits, allows for sufficient overheads such as addresses, packet framing and error detection/correction. Because the incidence of packets created by any one transmitter would be 60 or fewer per second including duplicates, TDM is possible because one transmitter 14 uses only 60/1000 or six percent of the channel, and ninety-four percent of the channel is available for other traffic.

Data packets are encapsulated so that layers of bit framing, error detection, address, and key 12 state information are encapsulated within the same packet. Error control and recovery can be accomplished with universal asynchronous receiver/transmitter (UART) oriented protocol. Alternatively, forward error correction can be implemented to eliminate the need for other error correction techniques. Guard patterns can be integrated for error detection, with guard bits in selected patterns surrounding data packets. If receiver 16 observed a defect in such guard patterns, receiver 16 would be alerted that the integrity of the packet had been breached.

An LED lamp such as display 22 can provide visual information regarding data received or transmitted by RF transmitter 14. Although the use of addresses permits time domain transmission between the correct transmitter 14 and receiver 16, controller 10 can be temporarily reprogrammed with the address code of a foreign receiver, enabling it to function with the foreign receiver for a period of time if required.

10

15

20

IR transmissions are typically realized utilizing data rates much lower than 56,000 bps. The IR technology consequently has a diminished ability to create very short burst transmissions which in turn limits the TDM possibilities.

Conventional IR controller solutions are limited to two controllers, whereas the invention can be incorporate one or more splitters or multitaps attached to receiver 16 to add additional controllers 10 to communicate with the same receiver 16. The higher data throughput provided by using RF provides suitable operation for advanced or next generation game controllers such as those utilizing analog joystick control.

A natural delay is built into data transmission regimes. Figure 5 illustrates the respective data transmission signals for IR and RF data signals. For example, for a hard-wire controller, the T1 delay can comprise a statistically number in the range $0 < T_1 < 6.6$ milliseconds.

In another embodiment of the invention, each controller can transmit data over separate channels within the RF spectrum. The flexibility to operate controllers over different channels, and to multiplex data transmission from different controllers over the same frequency, permits flexibility in the system capability to operate multiple controllers in the same room with one or more radio frequency receivers and electronic game devices. If TDM permits three controllers 10 on the same channel, a twelve controller system uses four frequencies or channels instead of twelve.

In addition to the speed capabilities of RF transmission techniques taught by the invention, a low duty cycle (six percent in the earlier example) of

10

15

20

transmitter 14 permits transmitter 14 to be turned off most of the time (ninety-four percent in this example). The energy saving feature of the invention is particularly important for portable game controllers subjected to long, continuous play periods. By conserving battery power, the system design of the invention provide for longer operating times for the same battery power, which minimizes game disruption.

Whereas time domain multiplexing is conventionally used in continuous data transmission utilizations, the invention uniquely uses time domain multiplexing to transmit real time data for the purpose of game control transmission. Event driven transmission provides enhanced responsiveness over polling and other techniques because data transmission occurs immediately after the occurrence of an event. The absence of a designated transmission time is energy efficient and provides greater flexibility in the transmission of more data packets. This feature reduces transmission delays and provides enhanced controller 10 responsiveness to the user. As used herein, the term "user" can comprise a person, another controller, or other mechanism.

Modulation of the RF signal can be accomplished with ASK, FSK,

Quadrature modulation, spread spectrum, or other techniques. Events can be
compressed to lower the event count and to assist time domain modulation. By
lowering the number of events, collisions will be reduced and more users can
function on each channel.

In another embodiment of the invention, RF can be combined with IR transmission in different ways. For example, force feedback of controller 10 can .

10

15

20

be implemented by shaking or vibrating controller 10 to provide operating feedback to the user. A reverse IR data path could be implemented to enable such a force feedback feature. A simple IR path could be implemented next to the RF path in the same or opposite direction to provide alternative data transmission capabilities as illustrated in Figure 6.

In another embodiment of the invention, listen-before-send capabilities can be added to controller 10. For example, a carrier detect on controller 10 could provide the capability of determining whether another controller is transmitting or not at a certain time. Having controller 10 listen for traffic prior to sending would reduce collisions dramatically. This would reduce the system dependence on redundant packet transmissions and would create increased TDM efficiencies by permitting more users per channel.

Gaming systems are preferably economic to manufacture, which requires the fewest number of components. Battery operation and long hours of continuous use dictate power efficiencies in remote components. Although different combinations are possible as described, single-channel is preferable to multi-channel communication even though TDM can be implemented to enhance both multi and single-channel systems. Burst transmission is preferable to continuous transmission, because TDM effectively uses brief signal transmissions. The simplicity of single-direction (simplex) is preferable to two-direction (duplex) even though duplex systems can be designed to work with TDM gaming systems disclosed herein. Asynchronous communication is preferable to synchronous communication because data links between multiple

controllers would not be required to synchronize the timing of multiple transmissions.

Although the invention has been described in terms of certain preferred embodiments, it will be apparent to those of ordinary skill in the art that modifications and improvements can be made to the inventive concepts herein without departing from the scope of the invention. The embodiments shown herein are merely illustrative of the inventive concepts and should not be interpreted as limiting the scope of the invention.

|----|--|
| 2 | WHAT IS CLAIMED IS: |
| 3 | |
| 4 | 1. A game controller for communicating between a user and an electronic |
| 5 | game device, comprising: |
| 6 | a housing; |
| 7 | a sensor attached to said housing and responsive to operation by the |
| 8 | user to generate signals; |
| 9 | a radio frequency sender engaged with said sensor, wherein said sender |
| 10 | is capable of time domain multiplexed transmission of said signals; and |
| 11 | a radio frequency receiver engaged with the electronic game device for |
| 12 | receiving the signals from said radio frequency sender. |
| 13 | • |
| 14 | 2. A game controller as recited in Claim 1, wherein said radio frequency |
| 15 | receiver is attached to the electronic game device. |
| 16 | |
| 17 | 3. A game controller as recited in Claim 1, wherein said radio frequency |
| 18 | receiver is capable of transmitting signals from the electronic game device to |
| 19 | said radio frequency sender. |
| 20 | |
| 21 | 4. A game controller as recited in Claim 3, wherein said sensor is |
| 22 | engaged with said radio frequency sender for detecting signals transmitted by |
| 23 | said radio frequency sender. |

| 24 | |
|----|--|
| 25 | 5. A game controller as recited in Claim 1, wherein said radio frequency |
| 26 | sender is capable of being turned off when said signals are not being |
| 27 | transmitted. |
| 28 | |
| 29 | 6. A game controller as recited in Claim 1, wherein said radio frequency |
| 30 | sender is capable of transmitting said signals in a plurality of discrete time |
| 31 | intervals. |
| 32 | |
| 33 | 7. A game controller as recited in Claim 1, wherein said signals are |
| 34 | transmitted at a frequency equal to or greater than 300 MHz. |
| 35 | |
| 36 | 8. A game controller system for communicating between at least two |
| 37 | users and an electronic game device, comprising: |
| 38 | a housing; |
| 39 | at least two sensors engaged with said housing and responsive to |
| 40 | operation by the persons to generate signals; |
| 41 | a radio frequency sender engaged with said sensors, wherein said sender |
| 42 | is capable of time domain multiplexed transmission of said signals; and |
| 43 | a radio frequency receiver engaged with the electronic game device for |
| 44 | receiving the signals from said radio frequency sender. |
| 15 | |

| 46 | 9. A game controller system as recited in Claim 8, wherein each sensor is |
|----|---|
| 47 | attached to a separate housing and is further engaged with said radio frequency |
| 48 | sender. |
| 49 | |
| 50 | 10. A game controller system as recited in Claim 8, wherein said sensor |
| 51 | and said receiver share a common address transmitted as one of said signals. |
| 52 | |
| 53 | 11. A game controller system as recited in Claim 8, wherein one or more |
| 54 | of said radio frequency senders are capable of transmitting signals to one or |
| 55 | more radio frequency receivers each engaged with a different electronic game |
| 56 | device. |
| 57 | |
| 58 | 12. A game controller system as recited in Claim 8, wherein said receiver |
| 59 | is capable of receiving signals from at least two radio frequency senders |
| 60 | operating on different channels. |
| 61 | |
| 62 | 13. A game controller system as recited in Claim 8, wherein said receiver |
| 63 | is capable of receiving signals from at least two radio frequency senders |
| 64 | operating on the same channel. |
| 65 | |
| 66 | |

| 67 | 14. A method for communicating between a user and an electronic game |
|----|---|
| 68 | device, comprising: |
| 69 | operating a sensor engaged with a housing to generate signals in |
| 70 | response to operation by the user; |
| 71 | detecting said signals with a radio frequency sender engaged with said |
| 72 | sensor; |
| 73 | operating said radio frequency sender to transmit said signals with time |
| 74 | domain multiplexing; and |
| 75 | receiving said radio frequency sender signals with a radio frequency |
| 76 | receiver engaged with the electronic game device. |
| 77 | |
| 78 | 15. A method as recited in Claim 14, further comprising the steps of |
| 79 | operating a second sensor engaged with said housing to generate a signals in |
| 80 | response to operation by a second user, and of detecting said signals with said |
| 81 | radio frequency sender for transmission to said radio frequency receiver. |
| 82 | |
| 83 | 16. A method as recited in Claim 14, further comprising the steps of |
| 84 | operating a second sensor engaged with a second housing to generate signals |
| 85 | in response to operation by a second user, of detecting said signals with a |
| 86 | second radio frequency sender engaged with said second sensor, of transmitting |
| 87 | said signals with said radio frequency sender, and of receiving said second radio |

frequency sender signals with said radio frequency receiver.

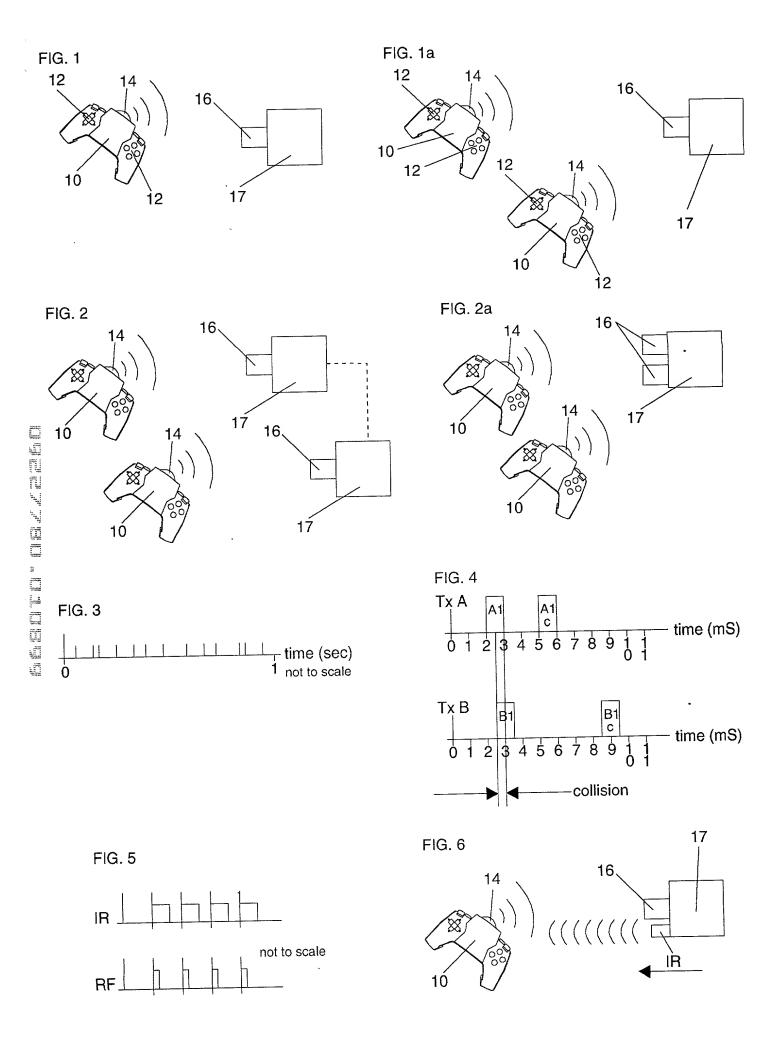

| 17. A method as recited in Claim 14, further comprising the steps of |
|---|
| transmitting signals from said radio frequency receiver and of receiving said |
| radio frequency receiver signals with said radio frequency sender. |

- 18. A method as recited in Claim 14, further comprising the step of transmitting the signals in a plurality of discrete time periods interrupted by periods where no transmission occurs.
 - 19. A method as recited in Claim 14, further comprising the step of transmitting signals between said radio frequency sender and said radio frequency receiver which comprise an address for connecting said sender and receiver.

15

ABSTRACT OF THE INVENTION

A portable game controller for operating an electronic game device. The controller communicates between a person and the game device with a radio frequency sender and receiver. Signal transmission is communicated over the same channel with time domain multiplexing, and can be sent over one or more channels to expand the number of controllers operable in a system. Signal transmission can be delivered in short intervals to conserve battery power. Multiple persons can deliver signals through multiple senders or through a common radio frequency sender, and signals can be transmitted from the radio frequency receiver to the radio frequency sender.

DECLARATION AND POWER OF ATTORNEY

We, John Sobota, Jason Gosier, Louis Gamer and Colin Broughton, hereby declare that we are the original and first inventors of the subject matter set forth in the Patent Application attached hereto and entitled:

"RADIO FREQUENCY REMOTE GAME CONTROLLER".

We have assigned all interest in the Patent and in the Patent Application to Eleven Engineering Incorporated. We further declare that our residences and home mailing addresses are set forth below, and that each of us is a citizen of Canada. We have reviewed and understand the contents of the referenced specification, including the claims, as amended by any amendment specifically referred to in this Declaration, and we acknowledge the duty to disclose information material to patentability in accordance with Title 37, CFR 1.56(a).

We appoint the following attorney to prosecute this Patent Application and to transact all business in the United States Patent and Trademark Office on our behalf, and direct that all correspondence be mailed to our attorney:

Alan J. Atkinson Registration No. 30,993 P. O. Box 270161 Houston, Texas 77277-0161.

We declare that all statements made herein of our own knowledge are true and correct and that all statements made on information and belief were made with the knowledge that willful false statements are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code, and that willful false statements may jeoperdize the validity of the Patent Application or any patent issued thereon. We declare under penalty of perjury under the laws of the United States of America that the foregoing is true and correct, as executed on the dates identified below.

Assignee:

Eleven Engineering Incorporated

Application: RADIO FREQUENCY REMOTE GAME CONTROLLER

I declare that Eleven Engineering Incorporated owns all rights to the referenced Patent Application and that Eleven Engineering Incorporated qualifies as a small business concern as defined in 37 CFR 1.9 for the purpose of paying reduced fees under Section 41(a) and (b) of Title 35, United States Code, to the Patent and Trademark Office with regard to the referenced Application, a specification of which is enclosed.

Eleven Engineering Incorporated has not assigned, granted, conveyed or licensed and is under no obligation under contract or law to assign, grant, convey or license, any rights in the invention to any person who could not be classified as an independent inventor under 37 CFR 1.9(c) if that person had made the invention, or to any concern which would not qualify as a small business concern or nonprofit organization under 37 CFR 1.9(e).

Eleven Engineering Incorporated acknowledges the duty to file in this Application, notification of any change in status resulting in loss of entitlement to small business concern status prior to paying, or at the time of paying, the earliest of the issue fee or any maintenance fee due after the date on which status as a small business concern is no longer appropriate.

On behalf of Eleven Engineering Incorporated I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true, and that these statements are made with the knowledge that willful false statements are punishable by fine or imprisonment, or both, and that willful false statements may jeopardize the validity of the Application, any patent issuing thereon, or any patent to which this verified statement is directed.
